From order request to proof of delivery: one B2B journey

Team PYRAMID · OnSite · Round 2 MVP

Erik, site manager at Nordbygg AB, needs cement and gypsum board for a project in Askim, Gothenburg. The MVP demonstrates this complete journey across the Round 1 pilot region: 10 stores and one hub in Sweden, using simulated data.

	1 Place order Tue 09:00	2 Validate & route seconds	3 Approve by node	4 Pick & dispatch next vehicle slot	5 Track until delivery	6 Confirm delivery on site	7 Measure pilot gate
Site manager customer	Pastes an order request (*"20 säckar Byggcement 25kg och 2 pall gips…"*), reviews the draft lines, corrects the gypsum quantity and places the order. Catalog & order → Paste an order message	Immediately sees whether the order can be fulfilled, how it is split across two nodes and why—or the exact shortfall. Order page: split bar and "why this node"			Tracks live status and ETA. If the forecast moves beyond the requested time, Erik receives a **proactive warning** before he needs to call. Order page, live updates, delay warning	Receives the goods and a confirmation showing the quantity delivered by each node and any shortfall. Order confirmation (not a tax invoice)	
OnSite system	AI · draft only Turns the request into draft lines. Contact details are removed first; every line must quote the source text; units are never converted; uncertain lines stay unselected.	Calculates usable stock as on hand − reserved − 10% buffer, but only when the feed is current and the node is reporting. Splits by earliest ETA: **54 + 46**; reserves at source.	Creates one task per node. Fulfilment starts only after every node approves. Reservations are held for 30 minutes while awaiting approval and renewed once approved.	Commits stock in the source system at dispatch and recalculates ETA using the vehicle slot, distance and unloading time.	Monitors every open order. If a node stops reporting, its unapproved share moves to the next node and any ETA change is pushed live.	Records the delivered quantity and whether the complete order arrived on time and in full (OTIF).	Sends privacy-filtered events to Central through a durable outbox and retries until they are accepted.
Store B & hub staff			Store B approves 54 bags and the hub approves 46. Each team sees only its own allocation and pick list. Staff → Tasks → task	Picks, stages and selects **Dispatch**. If a reservation has been lost, the task is blocked: nothing ships without reserved stock.		Confirms the delivered quantity—complete or short—with an optional note. Staff → task → Confirm delivery	
Head office							Pilot go/no-go card on Central, from Round 1: OTIF +3 pp · calls −30% · adoption >90%
Round 1 pain it removes	Manual re-keying introduces errors at the first step	Stock shortfalls surface only at loading	Store, hub and haulier lack a shared order status	Paper-based picking with no confirmation	~3 internal calls and ~20 min to answer "Where is my truck?"	Missing items lead to delivery disputes	No shared evidence that the pilot delivered value
Value	No re-keying; the customer validates every line	A credible promise before stock is reserved	One shared order; clear ownership by node	Stock is committed only when it ships	Proactive warning instead of a status call	A clear record of delivered quantities	Pilot KPIs calculated from operational events

Customer action · Deterministic system logic · AI suggestion, checked by a person · Store / hub staff · Head office

Resilience built into the customer journey

The Round 1 delivery problem becomes most visible when something goes wrong. Each scenario below is implemented in the MVP and covered by automated tests.

A. Not enough stock (scenario S2)

Erik requests 100 bags → Only 90 are usable (54 + 36). Nothing is reserved and no false promise is made → Sees a 10-bag shortfall and selects **Accept the 90 available** → Rechecks stock, reserves 54 + 36 and retains the original request of 100 for traceability

B. A store's server stops reporting (Round 1, Risk 3)

Store B stops reporting to the source system → After 5 minutes of silence, Store B is isolated from routing → Its unapproved allocation moves to the hub and the ETA is recalculated → Erik is notified only if the revised ETA is late

C. The AI is uncertain, incorrect or unavailable

A proposed line cannot be supported by a verbatim quote → The line is removed and recorded → Low confidence, unknown product or mismatched unit (pallet vs sheet) → The line stays unselected for Erik to decide. If the provider is unavailable, he orders from the catalog

D. A node says no, or a system is down

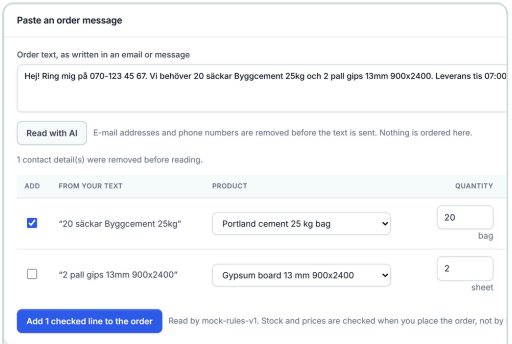

The hub rejects its task with a reason (forklift unavailable) → OnSite reallocates that share without returning it to the hub. If no node can fulfil it, all holds are released and Erik is informed → Source system unavailable: no promise is made. Central unavailable: orders continue and queued events catch up later

Before and after, for the same order

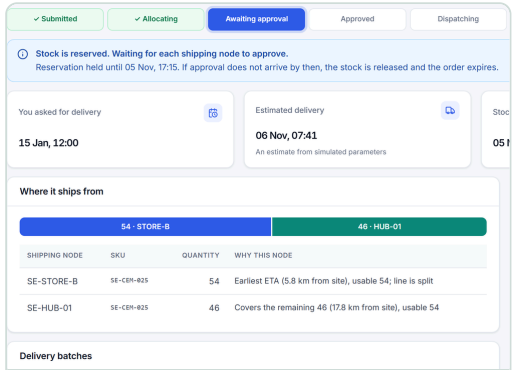

Moment	Before OnSite	With OnSite (MVP)
Placing the order	E-mail re-keyed by store staff	Text read into draft lines; the customer confirms each one
Is it in stock?	Staff check 11 locations one by one	One consolidated answer across all nodes, net of a 10% buffer
Not enough stock	Found at loading, next morning	Found while ordering; accept what is available or cancel
Two locations needed	Staff coordinate by phone	Rules-based split with the reason shown; each node approves its allocation
A store goes offline	Order silently stuck there	Isolated after 5 min; work moved to the next node
"Where is my delivery?"	~3 internal calls and ~20 min for an answer	Live ETA and a proactive warning before the customer needs to call
At delivery	Paper note and disputes	Quantity recorded by shipment; any short delivery is visible
Did the pilot work?	No shared evidence	Central reports OTIF, proactive warnings and adoption from privacy-filtered events

AI supports order intake only; deterministic rules control stock, routing, reservations and ETAs. All MVP figures are simulated. The "before" column comes from the Round 1 analysis (Thunberg & Persson 2014 and stated team assumptions), not measurements from this MVP.

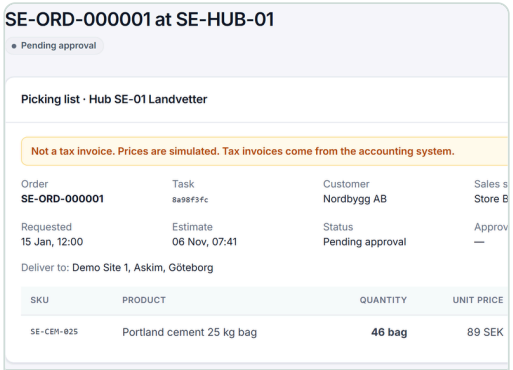

The same journey in the MVP

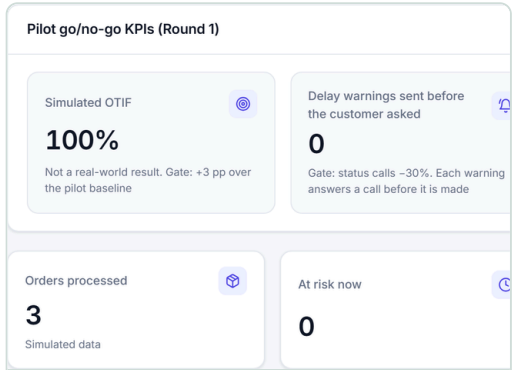

1 Paste an order request. Contact details are removed; cement is selected; "2 pall" is flagged as a unit mismatch for Erik to resolve.

2 Review the fulfilment plan. The 54 + 46 split, rationale, reservation deadline and history are visible.

3 Approve by node. The hub sees only its 46 bags; Store B has approved its share and the hub is next.

7 Measure the pilot. Central calculates the Round 1 go/no-go KPIs from filtered events (simulated data).
